1 Background

Researchers want to assess the effect of three different diets on the weight gain of fish. They have set up an experiment with 12 different tanks of fish. Each tank contains the same number of fish. The weight of 6 fish in each tank was measured at the beginning and the end of the experiment. The researchers recorded the weight gain.

2 Experimental design

- The explanatory variable in the experiment is the factor type of diet
- There are 3 diet types: diet 1, diet 2, and diet 3.
- The experimental unit is the tank: the diet treatments are adopted on the tanks, i.e., the tanks are randomized to the diet treatments.

- The weight gain is the response and it is measured on each fish which are the observational units.

Import libraries

```
library(tidyverse)
```

3 Data import

```
fish <- read.table("https://raw.githubusercontent.com/statOmics/PSLS21/data/fishTank.txt", header=TRUE)
head(fish)
```

```
##   Diet Tank WtGain
## 1    1    1    8.8
## 2    1    1    6.5
## 3    1    1   -1.1
## 4    1    1    1.3
## 5    1    1   -0.6
## 6    1    1    2.1
```

4 Tidy data

```
fish <- fish %>%
  mutate(Tank = as.factor(Tank), Diet = as.factor(Diet))
```

5 Data exploration

```
fish %>%
  ggplot(aes(x = Tank, y = WtGain, fill=Diet)) +
    geom_boxplot(outlier.shape=NA) +
    geom_jitter(width = 0.2) +
    ggtitle("Weight gain per tank") +
    ylab("Weight gain (g)") +
    stat_summary(fun = mean, geom="point", shape=5, size=3, color="black", fill="black") +
    scale_fill_brewer(palette="RdGy") +
    theme_bw()
```

6 Analysis

6.1 Pseudoreplication

- The diets are randomized to the tanks, hence, the tanks are the experimental units.
- We measure the weight of fish, they are the observational unit.
- We measure multiple fish for each tank, hence the fish of the same tank are **pseudoreplicates**. Indeed, fish from the same tank are exposed to more similar conditions and their measurements will be more similar and are thus not independent.
- If we do not account for this **pseudoreplication** our (regression) analysis and consider all fish as independent repeats, the standard error on the estimate for the diet effect will be underestimated, resulting in overly liberal inference.

To account for pseudoreplication in the data, we can average over the pseudoreplicates because we assess the same number fish in each tank. Hence, the tank averages will have an equal precision.

Note, that prior to averaging, the experimental unit was the tank, while the observational unit was the fish inside the tank. After averaging, the tank will be both the experimental and the observational unit of the experiment.

Averaging can be achieved with the `group_by` and `summarise` functions of the `dplyr` R package.

```
fish <- fish %>%
  group_by(Tank, Diet) %>%
  summarise(aveWtGain = mean(WtGain))
```

`summarise()` has grouped output by 'Tank'. You can override using the `.groups` argument.

```
fish
```

```
## # A tibble: 12 x 3
## # Groups:   Tank [12]
##   Tank Diet aveWtGain
##   <fct> <fct>     <dbl>
## 1 1 1     1         2.83
## 2 2 1     1         3.25
## 3 3 1     1         5.7
## 4 4 1     1         5.13
## 5 5 2     2        29.6
## 6 6 2     2         20
## 7 7 2     2        18.6
## 8 8 2     2        30.1
## 9 9 3     3        46.0
## 10 10 3     3        47.1
## 11 11 3     3        50.1
## 12 12 3     3        49.7
```

Now, the weight gain values are averaged over the six fish in each of the tanks.

6.2 Model assumptions

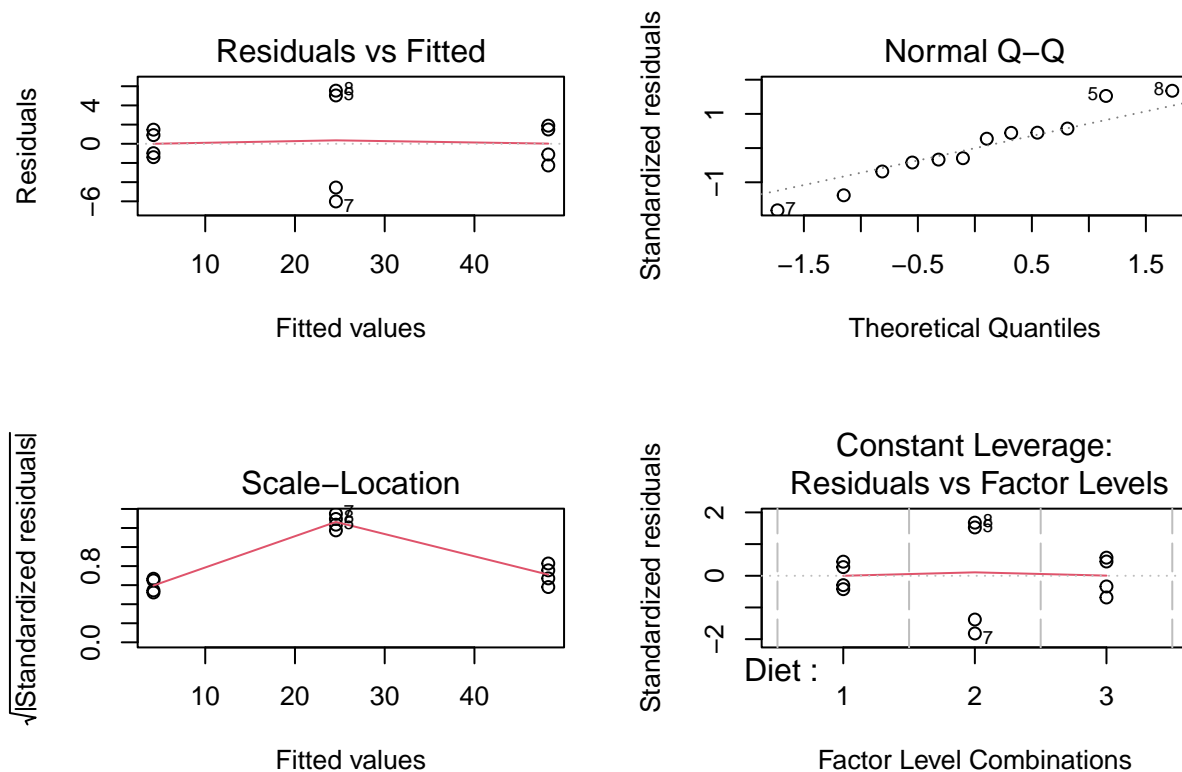

List assumptions:

1. The observations are independent
2. Linearity between the response and predictor variable
3. The residues of the model must be normally distributed
4. Homoscedasticity of the data

After averaging the weight gain values over the six fish in each of the tanks, we dealt with the pseudo-replication within tank and we expect the tanks to be independent repeats.

To assess the remaining assumptions, we first fit a linear regression model.

```
lmDiet <- lm(aveWtGain ~ Diet, fish)
par(mfrow=c(2,2))
plot(lmDiet)
```

We see some undesirable patterns in the diagnostic plots of the linear model.

While the smoother for assessing linearity in the data is flat and centered around zero, there is a much larger spread around the smoother for the observations (tanks) of the second diet type (tanks 5-8). These tanks are also flagged in the QQ-plot. Finally, the same tanks seem to have a larger variability in Diet 2 and/or additional tank/batch effects seem to occur. The tanks seem to cluster per two tanks and do not seem to be independent. We therefore have to be careful with the interpretation of the results.

6.3 Overall effect of diet

6.3.1 Test (ANOVA)

```
lmDiet <- lm(aveWtGain ~ Diet, fish)
library(car)
anova_diet <- Anova(lmDiet, type=3)
anova_diet
```

```
## Anova Table (Type III tests)
##
## Response: aveWtGain
##           Sum Sq Df F value    Pr(>F)
## (Intercept)  71.5  1   4.9142  0.05384 .
## Diet        3879.4  2 133.2349 2.059e-07 ***
## Residuals    131.0  9
```

```
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

There is an extremely significant effect of the diet on the average weight gain of fish ($p \ll 0.001$). *Note, that we have to be cautious with the interpretation due to the violation of the model assumptions*

6.4 Post-hoc analysis

```
library(multcomp)
multComp <- glht(model = lmDiet,
                 linfct = mcp(Diet = "Tukey"))
sumDiet <- summary(multComp)
sumDiet
```

```
##
##      Simultaneous Tests for General Linear Hypotheses
##
## Multiple Comparisons of Means: Tukey Contrasts
##
##
## Fit: lm(formula = aveWtGain ~ Diet, data = fish)
##
## Linear Hypotheses:
##      Estimate Std. Error t value Pr(>|t|)
## 2 - 1 == 0    20.333      2.698   7.536  <0.001 ***
## 3 - 1 == 0    44.000      2.698  16.308  <0.001 ***
## 3 - 2 == 0    23.667      2.698   8.772  <0.001 ***
## ---
## Signif. codes:  0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
## (Adjusted p values reported -- single-step method)
```

```
confDiet <- confint(multComp)
confDiet$confint
```

```
##      Estimate      lwr      upr
## 2 - 1 20.33333 12.80605 27.86061
## 3 - 1 44.00000 36.47272 51.52728
## 3 - 2 23.66667 16.13939 31.19395
## attr("conf.level")
## [1] 0.95
## attr("calpha")
## [1] 2.789936
```

6.5 Conclusion

There is an extremely significant effect of the diet on the average weight gain of fish ($p \ll 0.001$). The average weight gain of fish is extremely significantly different between all three diets (all $p \ll 0.001$).

The weight gain of fish in diet 3 is on average 44g and 23.7g higher than that for fish that were fed with diet 1 and 2, respectively (95% CI [36.5, 51.5] and [16.1, 31.2], respectively). The weight gain of fish in diet 2 is on average 20.3g higher than that for fish that were fed with diet 1 (95% CI [12.8, 27.9]).

Note, however, that the assumptions of test are violated, i.e. larger variability in Diet 2 and/or additional tank/batch effects in Diet 2. Indeed, the tanks seem to cluster per two tanks, which may indicate additional batch effects. **We therefore have to be very careful with the interpretation of the results.**
